Coupled THMC Processes under High Temperature in Bentonite Buffer: Laboratory Experiments, Field Tests, and Modeling

U.S. Nuclear Waste Technical Review Board
September 13-14, 2022

Liang Zheng, Chun Chang, Sangcheol Yoon, Sharon Borglin, Chunwei Chou, Jonny Rutqvist, Timothy Kneafsey, Yuxin Wu, Seiji Nakagawa, Luca Peruzzo, Jens Birkholzer

Lawrence Berkeley National Laboratory

To ensure favorable features of the bentonite in the long term, understanding and modeling of early-time thermal, hydrological, mechanical and chemical (THMC) perturbations is critical:

- **Thermal process**: Heat emission from waste and transport through bentonite buffer
- **Hydrological process**: Partially saturated bentonite becomes fully saturated after transient de-saturation and re-saturation
- **Mechanical process**: Stress evolution, possibly leading to damage
- **Chemical process**: Solute transport, radionuclide migration and mineralogical change

(Modified from Leupin et al, 2014)
Processes Involved in Bentonite Evolution (2)

THMC processes are coupled and evolve temporally and spatially

- Alteration of minerals with high solubility occurs in the early time period
- Alteration of clay minerals occurs in the late time period
- Stress rises and falls, eventually stabilizes
- Initially partially saturated
  - Desaturation
  - Re-saturation
  - Fully saturated
- Temperature in EBS increases and then decreases
- Heat emission decays

Time (year)
Processes model is the foundation of performance assessment model. To build such models, we need to know:

- What are the key processes that have to be included in the model?
- Do we have reliable constitutive relationships and parameters to describe THM processes?
  - Porosity and permeability changes
  - Stress evolution
- Do we have reliable chemical models and parameters to describe chemical processes?
  - Evolution of pore-water geochemistry in bentonite
  - Mineralogical changes in bentonite
  - Retardation capability
  - Interactions between canister/bentonite/host rock

Studies had focused on the THMC process under 100 °C
What If the Temperature is Higher (200 °C)?

Benefit

• Support Dual Purpose Canister disposal as it can lead to higher temperatures in the engineered and near-field natural barrier system
• Open the possibility of raising thermal limit of 100 °C for small PWR canisters
• Expanding the knowledge and data base to build the confidence

Key knowledge gaps to be narrowed

• When bentonite evolves from partial saturation to full saturation at temperatures up to 200 °C, how does bentonite change hydrologically and mechanically (e.g., boiling temperatures, high pore pressure, high stress, gas transport, etc.)?
• What are the mineralogical alterations of bentonite in the short-term and long-term (e.g., illitization and loss of swelling capacity)?
• Are the models (including processes, constitutive relationships and parameters) developed for 100 °C suitable for high temperature conditions?

Using generic models, laboratory experiments and field tests to address these questions
An Interactive and Iterative Approach

Goal

- Better understanding
- Reliable process model
- Gear toward performance assessment model

Approach

- Interaction between modeling and test
- Gradually increase the level of complexity test
- From low temperature to high temperature
- Synergy among multiple modeling/test efforts
- Revisit/revise the model
Experience Gained from Low Temperature THMC Test and Model (1)

An in situ test

The full-scale in situ test is located in Grimsel, Switzerland, heating started in 1997 at 100 °C, as part of FEBEX (Full-scale Engineered Barrier Experiment) (ENRESA, 2000).

In 2002, Dismantling of Heater #1

In 2015, Dismantling of Heater #2

Extensive laboratory tests were carried out to characterize THMC properties of bentonite, concrete, steel liner and granite.
Experience Gained from Low Temperature THMC Test and Model (2)

THMC modeling

Developing the model
- **Thermal model**: Heat convection and conduction
- **Flow model**: Two-phase (gas and water) flow
- **Mechanical model**: Poro-elastic using state surface approach
- **Chemical model**: Aqueous complexation, surface complexation, cation exchange and minerals dissolution/precipitation
- **Key coupled processes** needed to reproduce data: vapor diffusion, porosity and permeability change due to swelling, thermal osmosis

Testing the model with THMC data

Zheng et al. 2019
THMC modeling

- Complex model vs limited data
- Deficiency of some models were not revealed by short-term data
- Long-term measurements and multiple types of data are critical for reducing uncertainty and delineating right conceptual model and parameters

Zheng et al. 2019
Experience Gained from Low Temperature THMC Test and Model (4)

Understanding deepened and modeling capabilities improved

• Processes needed for modeling bentonite THM evolution:
  – Thermal conduction and convection
  – Multiphase flow
  – Poro-elasticity
  – Porosity and permeability changes due to swelling

• About geochemical evolution:
  – Ion concentrations in pore water are high near the heater, which were largely shaped by transport processes, but also affected by minerals and cation exchange
  – Alterations to carbonate minerals and gypsum happened in the entire bentonite barrier
  – Alterations to clay minerals were moderate and mostly occurred near the heater, which cannot be verified by the data that have large measurement uncertainties

• Key to increase the robustness of our predictive models for bentonite:
  – long-term measurements
  – Multiple types of data
• Chemical model: aqueous complexation, minerals dissolution/precipitation and cation exchangeable
• Illitization was modeled as smectite dissolution and precipitation of illite:
  \[ \text{Smectite} + 0.52\text{H}^+ + 0.63\text{AlO}_2^- + 0.6\text{K} = \text{illite} + 0.26\text{H}_2\text{O} + 0.08\text{Mg}^{2+} + 0.33\text{Na}^+ + 0.5\text{SiO}_2(\text{aq}) \]
• The reaction rate was calibrated against data from Kinnekulle bentonite, Sweden (Push and Madsen, 1995)
• Mechanical-chemical coupling was formulated via an extended linear swelling model or Dual structural Expansive Clay Model (BExM)

( Zheng et al., 2015; 2017)
Example of key results: illitization occurs, temperature plays a key role and bentonite-host rock interaction is important.

The temporal evolution of smectite volume fraction at points A, B, C, and D for Kunigel-VI bentonite.

At early times, dissolution of k-feldspar supplies K for illitization; after about 3000 years, illitization in host rock stops and K is transported into bentonite which leads to very different illitization at points A and B.
Average for inlet and outlet pressure has been 120 psi (8.3 bars). Flow is 0.11 mL/min.
After the bentonite was flooded for 1 day, heater was turned on at 150 °C.
After a week the temperature at the heater was maintained at 200 °C.

High temperature column experiment on bentonite
Laboratory Tests and Modeling (2)

High temperature column experiment on bentonite: Hydration showed by CT scan

CT density (g/cm³)

0 day 8 days
Non-heated

0 day 8 days
Heated

Heated column

564 days, precipitation growth
75 days, mineral precipitation initiated
40 days
8 days
4 days
22 days
2 days, heater on
1 day, hydration started
0 day, initial condition

Clay Sand
• Simulating the dynamic THM process is challenging
• Further refine of the mechanical model
• Temperature-dependent water retention curve
• Expansion to THMC model will be conducted after THM model is settled
HotBENT Field Experiment (1)

Location

Participating organizations

NAGRA (Switzerland), DOE (USA), NUMO (Japan), RWM (UK), SÚRAO (Czech Republic), NWMO (Canada), BGR (Germany); ENRESA (Spain), Obayashi (Japan)
Four modules
- Differing in heating temperature, bentonite, time length and w/o concrete liner

Two experimental time lengths
- H3 and H4 will run for 5-10 years
- H1 and H2 will run 15-20 years

Two bentonites
- Wyoming (MX-80)
- BCV (Czech Republic bentonite)

Two shapes
- Pedestals for the heaters made of highly compacted blocks, dry density > 1.7 g/cm³
- Granulated Bentonite Mixture (GBM), dry density > 1.45 g/cm³

Future experiment running and dismantling times to be decided by the partners.
Installation

HotBENT : Operational overview video:
https://grimsel.com/gts-projects/hotbent-high-temperature-effects-on-bentonite-buffers/hotbent-video
Instrumentation

Lot 1

Section E'
Measurements of:
- Temperature (T)
- Pore pressure (PP)
- Relative humidity (RH)

Lot 6

Section E'
Measurements of:
- Temperature (T)
- Pore pressure (PP)
- Relative humidity (RH)
- Total pressure (TP)
- Water content (WC)
- Displacement (D)

(Kober, 2020)
• Heating Started on Sep 9, 2021
• Heaters have been ramped up in steps.
• By June 2, all heaters reached their targeted temperature
HotBENT modeling platform was established

- Overarching goal:
  - Assess with “initial” modelling the capability of various approaches based on existing laboratory data and simplified assumptions to capture the behavior of the system
  - Interpret the observed behavior based on limited calibration (data release cycles) and predict (including uncertainty) the evolution of the system
  - Predict the state and inform in advance of the partial (and at a later stage full) dismantling activities.

SNL Modeling: THMC process at interfacial areas, e.g. metal corrosion at metal-buffer material interfaces
Coupled THMC model

**Goal:** Increase the predictability of THMC evolution of bentonite under high temperature: focusing on Improved constitutive relationships under high T, long term geochemical evolution and UQ.

**Ongoing:**
- 3-D TH model

**Next steps:**
- Expanding the 3-D TH model to THM model
- Make blind prediction of the 1-year response in the field test
- Refinement the model based on the goodness-of-fit of 1-year data
- Make long term prediction using the refined model
- Expanding the THM model to THMC model
- UQ for THMC model

**Code:** TOUGHREACT-FLAC3D, sequentially coupled THMC code

**Performance measure:** use as much data as possible in bentonite and geosphere
Integrating Coupled THMC models with Generic Disposal

- Developing advanced modeling tools
- Constructing multi-physics coupled process models
- Testing models with large scale experiments

Supplying generic Performance Assessment (PA) models with reliable conceptual model and parameters
- Providing generic PA models with well-tested constitutive relationships
- Integrating process models into PA
• Understanding and modeling of THMC perturbations in bentonite buffer is critical for clay repository.
• Experience was gained for THMC process under low temperature, but recent studies have been dedicated to high temperature conditions.
• Generic models, laboratory and field experiments and the corresponding modeling work have been conducted.
• Modeling and laboratory/field test are working iteratively and interactively to deepen understanding and improve modeling capability.
• Understanding of the alteration of bentonite buffer is enhanced and modeling capability is improved, which will be integrated into Generic Disposal Systems Analyses (GDSA) for performance assessment.
